ABSTRACT

This case illustrates a death of a man who had fallen from a height and managed for fracture of spine who had ultimately died of an unexpected, under-attended pathology.

A 35-year-old previously healthy man had a fall from a height and was admitted to a surgical ward with backache. He was diagnosed to have a fracture of the 12th thoracic and 1st lumbar vertebrae. On the 14th day after the fall he became confused but was not febrile. Condition worsened and he succumbed on the 15th day. Examination of the x-ray spine revealed the “fracture” of the 12th thoracic vertebra.

At autopsy a defect in the spine was detected with no associated hemorrhage. There was subcutaneous and muscle contusions of the right sacral area with no associated bony injuries. The kidneys were enlarged, congested, oedematous with multiple abscesses indicating acute pyelonephritis.

It may be concluded that other possibilities of back ache unrelated to trauma need to be considered in persons who fall from heights.

Key words:
Fall, Backache, Spine, Fracture, Pyelonephritis
INTRODUCTION

Congenital abnormalities mimicking fractures are rare. Most of these abnormalities are asymptomatic and are a diagnostic challenge to the treating physician. Unfortunately, conventional radiological imaging may be unhelpful in differentiating congenital abnormalities such as platyspondyly from fractures.

CASE REPORT

A 35-year-old previously healthy man had a fall from a height of 18 feet and was admitted to a surgical ward with backache. X-ray of the spine revealed a “wedge fracture” of the 12th thoracic vertebra (Fig. 1, 2).

There was no record of any significant past medical history including urinary tract infections or pyelonephritis. There was no recorded fever. Thus, the management was mainly directed towards orthopedic care, specially, stabilization of spine following referral to an orthopedic surgeon. In spite of the management he continued to have backache. On the 14th day after the fall he became confused, but was not febrile. The condition worsened and he succumbed on the 15th day.

Since it was considered to be a death following accidental trauma, an inquest was ordered and the body was subjected to a medico legal autopsy under the authority of the Inquirer in to Sudden Deaths. The body was that of a well-nourished and well-developed man, 64” in height. There were no external injuries. There was an anterior wedge shaped defect in the spine with no associated hemorrhage. There was subcutaneous and muscle contusion of the right sacral area with no associated bony injuries (Fig. 3).
The kidneys were enlarged, congested, oedematous with multiple abscesses. (Fig. 4).

Histology revealed acute on chronic pyelonephritis (Fig. 5). No other pathology was noted. The cause of death was concluded as pyelonephritis and the circumstance was natural.

DISCUSSION

There are four basic mechanisms of vertebral injuries: flexion, extension, shearing, and rotary movements.\textsuperscript{3,4} Lumber vertebral wedge fractures are known to occur in falls from height.\textsuperscript{5} Although back pain is often caused by injury and evidence of spinal trauma can easily be evaluated and is obvious, it is important to focus on other pathologies especially when the pain is not responding or worsening during the course of treatment. Attention should have been paid to exclude other potentially life threatening conditions.

Back pain may have many other underlying reasons. Aortic aneurysm, myocardial infarction, acute pancreatitis, duodenal ulcers, gynecological conditions, renal calculi, acute pyelonephritis and urinary tract infections are some of the serious conditions that can present with back pain needing urgent attention.\textsuperscript{6,7} This 35-year-old man was ultimately diagnosed to have pyelonephritis, which explains his worsening back pain irrespective of the management of trauma.

Pyelonephritis can cause lower back pain. The condition can be potentially lethal if unattended. Accurate and timely diagnosis and treatment can prevent serious complications.\textsuperscript{8}
When there is a congenital abnormality of the spine mimicking a fracture in a man who presents with backache after falling from a height, other possibilities of backache could be missed.

Subtle difference in the symptoms in other causes of backache and confusion due to referred pain may mislead physicians. The clinical diagnosis of pyelonephritis is made on the history, physical examination, and urine analysis. Pyelonephritis may result in high fever and costovertebral angle tenderness with pain over the costovertebral angle on percussion. However, absence of fever and attribution of loin tenderness to trauma could be the reasons for misdiagnosis in this case.

Differential diagnosis between vertebral fractures and congenital or preexisting abnormalities can present a major clinical challenge, especially when the presentation is post traumatic. In this regard, a careful radiological evaluation is essential in order to make a correct diagnosis. However, patients may have conditions that mimic the imaging appearance of a lesion. Developmental anomalies of vertebrae may occur anywhere throughout the length of the spine and could affect any part of the vertebrae. This patient had a non-hemorrhagic wedge shaped defect involving the anterior part of the 12th thoracic vertebral body, which is known as hemivertebrae. This defect can be asymptomatic especially when it involves the thoracic or lumbar spine. Congenital or developmental disorders of the spine are known to mimic fractures. Especially in falls from a height, anterior wedge fractures or compression fractures are commonly observed, which have a similar radiological appearance to this defect. However, at autopsy, absence of the haemorrhage confirmed that the condition was pre-existing.

In conclusion, when a potentially treatable condition is undetected till death, in a patient receiving medical care, the family, the public, as well as the judiciary, may raise the question of medical negligence. Successful conviction of medical negligence needs establishment of establishment of a doctor-patient relationship, harm to the patient, failure to provide the required standard of care under the circumstances by the doctor, and the harm being a result of such failure. In this case, the patient was admitted and managed for backache following trauma which establishes the doctor-patient relationship. He succumbed with worsening backache due to undetected and unattended pyelonephritis. Whether there is failure of any standard of care needs careful evaluation with application of Bolam as well as Bolitho’s principles. If there is evidence of failure of standard of care leading to non-diagnosis of pyelonephritis, supported by a responsible body of similar professionals considering the presentation and the presence of the misleading vertebral defect, this case could be considered as a case of medical negligence.
